# Pure extender premice

An *extender over  $M$*  is a system of compatible measures  $E = \langle E_a \mid a \in [\nu]^{<\omega} \rangle$  giving rise to an elementary  $i_E^M: M \rightarrow \text{Ult}(M, E)$ . We have

$$X \in E_a \text{ iff } a \in i_E(X).$$

We let  $\kappa_E = \text{crit}(i_E)$  and

$$\lambda_E = i_E(\kappa_E).$$

$E$  is *short* iff  $\nu \leq \lambda_E$  (so that  $E_a$  concentrates on  $[\kappa_E]^{|a|}$ .)  
A *pure extender premouse* is a structure  $M$  constructed from a coherent sequence  $\dot{E}^M$  of extenders. *Coherence* means the extenders are added in order of increasing strength (Mitchell order), without leaving gaps.

The notions are essentially due to W. Mitchell (1974, 1978).

In the active case,  $F$  is a short extender over  $M$  with support  $\lambda_F$ . We set  $\text{lh}(F) = o(M)$ .

If  $M$  is a proper initial segment of some premouse  $N$ , then  $F = \dot{E}_{\text{lh}(F)}^N$ . It may be that  $N$  has subsets of  $\kappa_F$  that are not in  $M$ , in which case  $F$  is *not* an extender over  $N$ !  $F$  only measures the subsets of  $\kappa_F$  that got into the model before we added  $F$ . (The Baldwin-Mitchell idea.)

To make this work we need a fine structural analysis of the first level of  $N$  over which a new subset of  $\kappa_F$  is definable.

The main further requirements on  $F$  are

- (1) ( $\lambda$ -indexing)  $M \models \kappa^+$  exists, and  $o(M) = \text{lh}(F) = \lambda_F^{+,M}$ .  $\dot{F}^M$  is the graph of  $i_F^M \upharpoonright (M \upharpoonright \kappa^+, M)$ .
- (2) (Coherence)  $i_F^M(\dot{E}^M) \upharpoonright o(M) + 1 = (\dot{E}^M) \frown \langle \emptyset \rangle$ .
- (3) (Initial segment condition, J-ISC) If  $G$  is a whole proper initial segment of  $F$ , then  $G$  must appear in  $\dot{E}^M$ . If there is a largest whole proper initial segment, then  $\dot{\gamma}^M$  is its index in  $\dot{E}^M$ . Otherwise,  $\dot{\gamma}^M = 0$ .
- (4) If  $N$  is a proper initial segment of  $M$ , then  $N$  is a potential premouse.

Here an initial segment

$$G = F \upharpoonright \eta =_{df} F \cap ([\eta]^{<\omega} \times M)$$

of  $F$  is *whole* iff  $\eta = \lambda_G$ .

# Soundness

The basic fine structural notions apply to potential premice.

$$\rho_1(M) = \text{least } \alpha \text{ s.t. } \exists r \in M(\text{Th}_{\Sigma_1}^M(\alpha \cup \{r\}) \notin M),$$

$$p_1(M) = \text{first standard parameter of } M$$

= lex-least descending sequence of ordinals  $r$

such that  $\text{Th}_{\Sigma_1}^M(\rho_1(M) \cup r) \notin M$ .

We allow  $\rho_1(M) = o(M)$  and  $p_1(M) = \emptyset$ . One can define  $\rho_n(M)$  and  $p_n(M)$  in a similar way.

Premice are acceptable  $J$ -structures, and the key to their fine structure is that if they are sufficiently iterable, then their standard parameters are solid and universal.

Approximate definitions: for  $\rho = \rho_1(M)$  and  $p = p_1(M)$ ,

(1)  $p$  is *1-solid* iff the function  $q \mapsto \text{Th}_1^M(\rho \cup q)$ , defined on parameters  $q <_{\text{lex}} p$ , belongs to  $M$ .

(2)  $p$  is *1-universal* iff  $P(\rho)^M \subseteq \text{cHull}_1^M(\rho \cup p)$ .

1-solidity is used to show that if  $i: M \rightarrow N = \text{Ult}_0(M, E)$  is the canonical embedding, then  $i(p_1(M)) = p_1(N)$ .

### Definition

$M$  is *1-solid* iff  $p_1(M)$  is 1-solid and 1-universal.  $M$  is *1-sound* iff in addition  $M = \text{Hull}_1^M(\rho_1(M) \cup p_1(M))$ .

*Remark.* Suppose  $M$  is 1-sound, and  $N = \text{Ult}_0(M, E)$  where  $\rho_1(M) \leq \kappa_E$ ; then  $M$  is the 1-core of  $N$ , and  $i_E^M$  is the anticore map. That is,  $M = \text{cHull}_1^N(\rho_1(N) \cup p_1(N))$ , and  $i_E^M$  is the anticollapse.

## Definition

A *pure extender premouse* is a potential premouse all of whose proper initial segments are  $n$ -sound for all  $n$ .

If  $M$  is a premouse, then for all  $\kappa$ ,  $P(\kappa) \cap M \subseteq M \upharpoonright (\kappa^+)^M$ .  
This is a strong, local form of GCH.

For the mice we construct, solidity and universality are proved by comparison arguments, in an induction that keeps pace with the construction. To obtain soundness, we simply replace the current  $M$  by the appropriate hull (core) of  $M$ . (I.e. *core down*.) Universality is used to see that we don't lose too much when we core down; for example, we never lose subsets of  $\omega$ .

# The iteration game

Let  $M$  be a premouse. In  $\mathcal{G}(M, \theta)$ , players I and II play for  $\theta$  rounds, producing a tree  $\mathcal{T}$  of models, with embeddings along its branches, and  $M = \mathcal{M}_0^{\mathcal{T}}$  at the base.

*Round  $\alpha + 1$ :* I picks an extender  $E_\alpha^{\mathcal{T}}$  from the sequence of  $\mathcal{M}_\alpha^{\mathcal{T}}$  with support  $\geq$  the supports of all earlier extenders chosen. Let  $\beta$  be least such that  $\text{crit}(E_\alpha^{\mathcal{T}}) < \text{support}(E_\beta^{\mathcal{T}})$ . We set

$$\beta = T\text{-pred}(\alpha + 1),$$

and

$$\mathcal{M}_{\alpha+1}^{\mathcal{T}} = \text{Ult}_k(\mathcal{M}_\beta^{\mathcal{T}} | \eta, E_\alpha^{\mathcal{T}}),$$

where  $\langle \eta, k \rangle$  is as large as possible. If  $E_\alpha$  is not applied to all of  $\mathcal{M}_\beta$ , we say that  $\mathcal{T}$  *drops* at  $\alpha + 1$ , and put  $\alpha + 1 \in D^{\mathcal{T}}$ .

If  $\mathcal{M}_{\alpha+1}^{\mathcal{T}}$  is illfounded, then the game is over and I wins.

Round  $\lambda$ , for  $\lambda$  limit: II must pick a branch  $b$  of  $\mathcal{T}$  which is cofinal in  $\lambda$  such that  $D^\mathcal{T} \cap b$  is finite, and

$$\mathcal{M}_b^\mathcal{T} =_{df} \text{dirlim}_{\alpha \in (b - \text{sup} D^\mathcal{T})} \mathcal{M}_\alpha^\mathcal{T}$$

is wellfounded. If he fails to do so, I wins and the game is over. If he succeeds, then we set

$$\mathcal{M}_\lambda^\mathcal{T} = \text{dirlim}_{\alpha \in (b - \text{sup} D^\mathcal{T})} \mathcal{M}_\alpha^\mathcal{T}$$

and continue.

If I has not won at some round  $\alpha < \theta$ , then II wins.

A play of  $\mathcal{G}(M, \theta)$  in which II has not yet lost is called a *normal iteration tree* on  $M$ .

## Definition

A  $\theta$ -iteration strategy for  $M$  is a winning strategy for II in  $\mathcal{G}(M, \theta)$ . We say  $M$  is  $\theta$ -iterable just in case there is such a strategy. If  $\Sigma$  is a strategy for II in  $\mathcal{G}(M, \theta)$ , and  $P = \mathcal{M}_\alpha^\mathcal{T}$  for some  $\mathcal{T}$  played by  $\Sigma$ , then we call  $P$  a  $\Sigma$ -iterate of  $M$ .

## Definition

$M \sqsubseteq N$  iff  $M$  is an initial segment of  $N$ , and  $M \triangleleft N$  iff  $M \sqsubseteq N$  and  $M \neq N$ .

## Lemma (Comparison, Martin, Mitchell, S. 1985-89)

Let  $\Sigma$  and  $\Gamma$  be  $\theta + 1$  iteration strategies for  $P$  and  $Q$  respectively, where  $\theta = \max(|P|, |Q|)^+$ ; then there are a  $\Sigma$ -iterate  $R$  of  $P$  and a  $\Gamma$ -iterate  $S$  of  $Q$  such that either

- (a)  $R \triangleleft S$  and the branch  $P$ -to- $R$  does not drop, or
- (b)  $S \triangleleft R$  and the branch  $Q$ -to- $S$  does not drop.

# Proof sketch

For definiteness, let  $P$  and  $Q$  be countable, so that  $\Sigma$  and  $\Gamma$  are  $\omega_1 + 1$ -iteration strategies.

We build padded iteration trees  $\mathcal{T}$  on  $P$  and  $\mathcal{U}$  on  $Q$  inductively, by “iterating away the least disagreement” at successor steps, and using our iteration strategies at limit steps. Notation:

$\mathcal{T}$  : models  $P_\alpha$ , extenders  $E_\alpha$ ,

$\mathcal{U}$  : models  $Q_\alpha$ , extenders  $F_\alpha$ .

At step  $\alpha + 1$ , let

$\gamma = \text{least } \beta \text{ such that } P_\alpha|_\beta \neq Q_\alpha|_\beta.$

If there is no such  $\beta$ , the comparison terminates.

Otherwise,

$$E_\alpha = \dot{F}_\gamma^{P_\alpha|\gamma}, \text{ and}$$
$$F_\alpha = \dot{F}_\gamma^{Q_\alpha|\gamma}.$$

The rest of step  $\alpha + 1$  is determined by the rules for normal, padded iteration trees. ( If e.g.  $F_\alpha = \emptyset$ , then  $P_{\alpha+1} = P_\alpha$ .)

At limit steps we let  $\mathcal{T} \upharpoonright \lambda + 1$  be  $\bigcup_{\alpha < \lambda} \mathcal{T} \upharpoonright \alpha$ , extended by the branch  $\Sigma(\bigcup_{\alpha < \lambda} \mathcal{T} \upharpoonright \alpha)$  if this tree has limit length. Similarly on the  $\mathcal{U}$  side.

## Corollary

If  $P$  and  $Q$  are  $\omega_1 + 1$ -iterable, then  $P|_\alpha = Q|_\alpha$ , where  $\alpha = \inf(\omega_1^P, \omega_1^Q)$ . That is, their canonical wellorders of the reals by stage-of-construction are compatible.

*Proof.* If  $P$ -to- $R$  does not drop, then  $P|_{\omega_1^P} = R|_{\omega_1^R}$ . So we can apply the comparison lemma.  $\square$

## Corollary

If  $P$  is an  $\omega_1 + 1$ -iterable premouse, and  $x \in \mathbb{R} \cap P$ , then  $x$  is ordinal definable.

*Proof.* Let  $x$  be the  $\alpha$ -th real in  $P$ . Then  $y = x$  iff  $y$  is the  $\alpha$ -th real in some  $\omega_1 + 1$ -iterable premouse.  $\square$

## Generically absolute definitions

### Corollary

*Assume AD. Let  $x \in \mathbb{R} \cap P$ , where  $P$  is an  $\omega_1$ -iterable countable mouse; then  $x$  is  $\Sigma_1^2$  in a countable ordinal.*

### Proof.

Under AD,  $\omega_1$  is measurable, so countable  $\omega_1$ -iterable mice are  $\omega_1 + 1$ -iterable. If  $\Sigma$  is an  $\omega_1$  strategy, then  $\Sigma$  can be coded by set of reals, so “ $x$  is the  $\alpha$ -th real in some  $\omega_1$ -iterable mouse” is  $\Sigma_1^2$ . □

### Corollary

*Assume there are arbitrarily large Woodin cardinals, and let  $P$  be a countable mouse with an  $\omega_1$ -iteration strategy that is coded by a  $\text{Hom}_\infty$  set of reals; then every real in  $P$  is  $(\Sigma_1^2)^{\text{Hom}_\infty}$  in a countable ordinal.*

What about the converse—how far do the mice go?

## Definition

*Mouse Capturing* (MC) is the statement: for all reals  $x$  and  $y$ , if  $x$  is  $\Sigma_1^2(y)$  in a countable ordinal, then there is an  $\omega_1$ -iterable  $y$ -premouse  $M$  such that  $x \in M$ .

## Theorem (Woodin 1990s, Sargsyan 2009)

*Assume  $AD^+$ , and suppose there is no boldface pointclass  $\Gamma$  such that  $L(\Gamma, \mathbb{R}) \models AD_{\mathbb{R}} + \text{“}\theta \text{ is regular”}$ ; then Mouse Capturing holds.*

# Strategy uniqueness

We don't have a full comparison lemma or a mouse order yet, because how two mice compare might depend on the iteration strategies that are used to compare them. This can happen if the mice have Woodin cardinals. But otherwise, their iteration strategies are unique, and we do have a full comparison, and a mouse order.

## Definition

A premouse  $M$  is  $Q$ -full iff  $M$  has a largest cardinal, and whenever  $M \models \delta$  is Woodin, then  $\rho_\omega(M) < \delta$ .

*Examples:*

- (1) Any mouse cut at a successor cardinal below its bottom Woodin.
- (2) Any active premouse that projects to  $\omega$  (e.g.  $M_n^\sharp, M_\omega^\sharp$ ).
- (3) Not  $M_n$  or  $M_\omega$ .

## Theorem

*Suppose  $M$  is sound and  $Q$ -full; then  $M$  has at most one  $|M|^+ + 1$ -iteration strategy.*

*Proof.* Suppose  $\Sigma$  and  $\Gamma$  are distinct strategies, and  $\Sigma(\mathcal{T}) = b$  and  $\Gamma(\mathcal{T}) = c$  where  $b \neq c$ . Set

$$\delta = \delta(\mathcal{T}) = \sup(\{\text{lh}(E_\alpha^\mathcal{T}) \mid \alpha < \text{lh}(\mathcal{T})\}).$$

### **Lemma (Martin, S., 1985)**

$\delta$  is Woodin in  $\mathcal{M}_b^\mathcal{T}$  and  $\mathcal{M}_c^\mathcal{T}$  with respect to all  $f: \delta \rightarrow \delta$  such that  $f \in \mathcal{M}_b^\mathcal{T} \cap \mathcal{M}_c^\mathcal{T}$ .

We now compare  $\mathcal{T} \hat{\ } b$  with  $\mathcal{T} \hat{\ } c$ , using  $\Sigma$  and  $\Gamma$  to continue the two trees.

This results in trees  $\mathcal{U}$  and  $\mathcal{V}$  extending  $\mathcal{T} \hat{\ } b$  and  $\mathcal{T} \hat{\ } c$  with last models  $R$  and  $S$ . We may assume wlog that  $R \trianglelefteq S$ . Then

$$P(\delta)^R \subseteq \mathcal{M}_b^T \cap \mathcal{M}_c^T,$$

so

$R \models \delta$  is Woodin.

So  $M$ -to- $R$  has dropped, and  $R$  is unsound. Thus  $R = S$ ,  $S$  is unsound, and  $M$ -to- $S$  drops. Letting  $i: C \rightarrow R$  and  $j: C \rightarrow S$  be the branch embeddings of  $\mathcal{U}$  and  $\mathcal{V}$ , we get  $i = j =$  anticore map. This means  $C$ -to- $R$  and  $C$ -to- $S$  use the same sequence of extenders. This is impossible.  $\square$

# Stacks of normal trees

## Definition

$G(M, \lambda, \theta)$  is the game in which the players play  $\lambda$  rounds, the  $\alpha$ -th round being a play of  $G(N, \theta)$ , where  $N$  is the last model of round  $\alpha - 1$ , or the direct limit along the branch produced by the prior rounds if  $\alpha$  is a limit.

In  $G(M, \lambda, \theta)$  I moves at successor stages, by playing an extender or starting a new round if he wishes. If the current round lasts  $\theta$  moves, then there are no further rounds, and the game is over.

II picks branches at limit stages, and his obligation is just to insure all models are wellfounded, including the direct limit of the base models in the final stack of length  $\lambda$ .

## Definition

A  $(\lambda, \theta)$ -iteration strategy for  $M$  is a winning strategy for  $\text{II}$  in  $G(M, \lambda, \theta)$ .

A  $Q$ -full  $M$  can have at most one  $(\lambda, |M|^+ + 1)$ -iteration strategy, by the proof for  $\lambda = 1$  given above.

## Definition

Let  $M$  be a premouse; then  $M$  is *countably iterable* iff every countable elementary submodel of  $M$  is  $(\omega_1, \omega_1 + 1)$ -iterable.

Countable iterability is what one needs to prove that  $M$  is well-behaved in a fine structural sense; for example, that its standard parameter is solid and universal.

Since the copy maps commute with the branch embeddings, at limit steps  $\lambda$  we have a unique elementary  $\pi_\lambda: M_\lambda \rightarrow N_\lambda$  that commutes with the branch embeddings of  $\mathcal{T}$  and  $\pi\mathcal{T}$  along  $[0, \lambda)_{\mathcal{T}}$ . It is easy to check (1) and (2).

If  $\pi\mathcal{T}$  ever reaches an illfounded model, we stop the construction.

We can copy stacks of plus trees by successively copying the individual plus trees in the stack.

# The Dodd-Jensen Lemma

## Lemma (Dodd-Jensen)

Let  $M$  be  $Q$ -full, and  $(\theta, \theta + 1)$ -iterable, where  $\theta = |M|^+$ . Let  $\Sigma$  be the unique  $(\theta, \theta + 1)$  strategy for  $M$ , and  $s$  a stack by  $\Sigma$  with last model  $N$ , and let

$$\pi: M \rightarrow P \trianglelefteq N$$

be elementary; then

- (1) the branch  $M$ -to- $N$  of  $s$  does not drop,  $P = N$ , and
- (2) for  $i: M \rightarrow N$  the iteration map,  $i(\eta) \leq \pi(\eta)$  for all  $\eta < o(M)$ .

*Proof.* It is crucial that  $(\Sigma_s)^\pi = \Sigma$ . This follows from the uniqueness of  $\Sigma$ . □

Introduction

Strategy uniqueness, Dodd-Jensen, and the mouse order

Mouse pairs

Comparison of mouse pairs

Hod pair capturing

Mouse limits and Suslin cardinals

Determinacy models from hod pairs

So the iteration maps on  $Q$ -full, iterable mice are pointwise minimal. This implies they are unique.

### Corollary

*Let  $M$  be  $Q$ -full, and  $(\theta, \theta + 1)$ -iterable, where  $\theta = |M|^+$ . Let  $\Sigma$  be the unique  $(\theta, \theta + 1)$  strategy for  $M$ , and  $s$  and  $t$  stacks by  $\Sigma$  with last models  $P$  and  $Q$  such that  $P \trianglelefteq Q$ . Then  $P = Q$ , and if  $M$ -to- $P$  does not drop, then  $M$ -to- $Q$  does not drop, and the two iteration maps are equal.*

*Remark* There can be distinct non-dropping stacks going from  $M$ -to- $N$ . It's just the iteration maps that must be equal.

# The mouse order on $Q$ -full mice.

Because it is the most important context for us, we shall assume  $AD^+$  and consider only countable mice. Let  $M$  and  $N$  be countable,  $Q$ -full,  $(\omega_1, \omega_1)$ -iterable premice then

$$M \leq^* N \text{ iff } \exists R, S, \pi (S \text{ is a countable iterate of } N \\ \wedge R \trianglelefteq S \wedge \pi: M \rightarrow R \text{ is elementary}).$$

Using Dodd-Jensen, one gets that  $M \leq^* N$  iff when you compare them via least disagreement, with last models  $R$  on the  $M$  side and  $S$  on the  $N$  side, then  $M$ -to- $R$  doesn't drop and  $R \trianglelefteq S$ . Show  $M <^* N$  iff either  $R \triangleleft S$  or  $N$ -to- $S$  drops.

Determinacy models from hod pairs

# Mouse limits and HOD

Assume  $AD^+$ , and let  $P$  be countable,  $Q$ -full, and  $(\omega_1, \omega_1)$ -iterable. We define a direct limit system  $(\mathcal{F}_P, \prec)$  by

$Q \in \mathcal{F}_P$  iff  $Q$  is a countable, non-dropping iterate of  $P$ ,

and for  $Q, R \in \mathcal{F}_P$ ,

$Q \prec R$  iff  $R$  is a non-dropping iterate of  $Q$ .

For  $Q \prec R$ , let  $\pi_{Q,R}: Q \rightarrow R$  be the (unique) iteration map; then we set

$$M_\infty(P) = \text{dirlim}(\mathcal{F}_P, \prec),$$

where the direct limit is under the  $\pi_{Q,R}$  for  $Q \prec R$ .  $(\mathcal{F}_P, \prec)$  is countably directed, so  $M_\infty(P)$  is wellfounded, and we then take it to be transitive.

Introduction

*Remarks.* Assume  $AD^+$ .

(a)  $P \equiv^* Q$  iff  $M_\infty(P) = M_\infty(Q)$ .

(b)  $M_\infty(P) \in \text{HOD}$ .

(c)  $o(M_\infty(P)) < \text{boldface } \delta_1^2$ .

### Definition

$P$  is *full* iff  $P$  is  $Q$ -full, and whenever  $P \leq^* Q$ , then  $M_\infty(P) \trianglelefteq M_\infty(Q)$ .

### Theorem (S. 1994)

*Assume  $AD^+$ , and suppose Mouse Capturing holds; then*

$$\text{HOD} \upharpoonright \delta_1^2 = \bigcup_{P \text{ full}} M_\infty(P).$$

So under these hypotheses,  $\text{HOD} \upharpoonright \delta_1^2$  is a premouse, and in particular satisfies GCH.

# Mouse pairs

We'd like a full comparison theorem for mice with Woodin cardinals, but their iteration strategies are not unique. We need to compare the strategies too, i.e. to compare *pairs* consisting of a mouse and an iteration strategy for it. This requires that the iteration strategies have certain regularity properties: strong hull condensation, normalizing well, and internal lift consistency.

## Normalizing well

For  $\langle \mathcal{T}, \mathcal{U} \rangle$  a stack on  $P$ , we can re-order the use of extenders so as to produce a normal tree  $\mathcal{W} = W(\mathcal{T}, \mathcal{U})$ , and an embedding of the last model of  $\mathcal{U}$  into the last model of  $\mathcal{W}$ . We call  $W(\mathcal{T}, \mathcal{U})$  the *embedding normalization* of the stack  $\langle \mathcal{T}, \mathcal{U} \rangle$ .

Then  $\Sigma$  2-normalizes well iff

$\langle \mathcal{T}, \mathcal{U} \rangle$  is by  $\Sigma$  iff  $W(\mathcal{T}, \mathcal{U})$  is by  $\Sigma$ ,

and

$$\Sigma_{\langle \mathcal{W} \rangle}^{\pi} = \Sigma_{\langle \mathcal{T}, \mathcal{U} \rangle}.$$

for all such stacks  $\langle \mathcal{T}, \mathcal{U} \rangle$ .  $\Sigma$  normalizes well iff all its tails

## Theorem (Woodin, late 1980s)

(AD<sup>+</sup>) For any Suslin-co-Suslin set  $B$ , there is an  $(N, \tau, \delta, \Sigma)$  that coarsely captures  $B$ .

This means:

- (a)  $N$  is countable,  $N \models \text{ZFC} + \text{“}\delta \text{ is Woodin”}$ ,
- (b)  $\Sigma$  is an iteration strategy for  $N$  defined on all  $s \in \text{HC}$ , and  $\Sigma \upharpoonright V_\delta^N \in N$ , and
- (c) if  $i: N \rightarrow M$  is an iteration map by  $\Sigma$ , and  $g$  is  $\text{Col}(\omega, i(\delta))$ -generic over  $M$ , then  $i(\tau)_g = B \cap M[g]$ .

Strategy uniqueness, Dodd-Jensen, and the mouse order

Mouse pairs

Comparison of mouse pairs

Hod pair capturing

Mouse limits and Suslin cardinals

Determinacy models from hod pairs

Inside  $N$ , we have the maximal (pure extender, lbr hod) pair construction  $\langle (M_{\nu,k}, \Omega_{\nu,k}) \mid \langle \nu, k \rangle \leq_{\text{lex}} \langle \delta, 0 \rangle \rangle$ :

- (a) each  $(M_{\nu,k}, \Omega_{\nu,k})$  is a mouse pair,
- (b) an  $E$  gets added to the sequence of  $M_{\nu,0}$  whenever doing so produces a premouse, and  $E$  extends to a nice extender  $E^*$  in  $N$ ,
- (c)  $\Omega_{\nu,k}$  is the strategy for  $M_{\nu,k}$  that is induced by  $\Sigma$ ,
- (d) information about  $\Omega_{\nu,k}$  is inserted at strategy-active stages, and
- (e)  $(M_{\nu,k+1}, \Omega_{\nu,k+1}) = \text{core}(M_{\nu,k}, \Omega_{\nu,k})$ .

Comparison arguments show that the construction never breaks down; all levels are mouse pairs whose cores exist, and the  $E$  added in (b) is unique.

- (b)  $(P, \Sigma)$  iterates strictly past all levels of  $\mathbb{C}$  that are strictly earlier than  $(M, \Omega)$ .*

Let us sketch why no strategy disagreements show up when we compare  $(P, \Sigma)$  with a level  $(R, \Lambda)$  of  $\mathbb{C}$ . Let  $\mathcal{T}$  from  $P$  to  $R$  be by  $\Sigma$ . Let  $\mathcal{U}$  on  $R$  be by both  $\Sigma_{\langle \mathcal{T} \rangle}$  and  $\Lambda$ , and let  $\Lambda(\mathcal{T}) = b$ . We must show  $\langle \mathcal{T}, \mathcal{U} \cap b \rangle$  is by  $\Sigma$ . Let  $\mathcal{W}_b = W(\mathcal{T}, \mathcal{U} \cap b)$  be its embedding normalization.

# Least disagreement comparison

A more effective comparison process yields

## Theorem (Sargsyan, S. 2024)

*Assume  $AD^+$ , and let  $(P, \Sigma)$  and  $(Q, \Psi)$  be mouse pairs of the same type such that  $P$  and  $Q$  are countable and coded by reals  $x_P, x_Q$ . Let  $T_\Sigma$  and  $T_\Psi$  be Suslin representations of the codesets of the two strategies; then  $(P, \Sigma)$  and  $(Q, \Psi)$  have a common iterate  $(R, \Phi)$  such that  $R$  is countable in  $L[x_P, x_Q, T_\Sigma, T_\Psi]$ .*

That the more effective process succeeds relies on results proved using the less effective one.

Comparison of mouse pairs

Hod pair capturing

Mouse limits and Suslin cardinals

Determinacy models from hod pairs

# Hod pair capturing

Least branch hod pairs can be used to compute HOD, provided that there are enough of them.

## Definition

( $AD^+$ ) *HOD pair capturing* (HPC) is the statement: for every Suslin, co-Suslin set of reals  $A$ , there is an lbr hod pair  $(P, \Sigma)$  with scope HC such that  $A$  is definable over  $(HC, \in, \Sigma)$ .

## Remarks.

- (a) Under  $AD^+$ , if  $(P, \Sigma)$  is a mouse pair, then  $\text{Code}(\Sigma)$  is Suslin and co-Suslin.
- (b) HPC implies that every Suslin-co-Suslin set of reals  $A$  is in a symmetric extension of some hod pair  $(P, \Sigma)$ . So the theory of  $L(A, \mathbb{R})$  is definable over  $P$ .
- (c) MC implies HPC. We would guess the converse is true, but do not have a proof.

## Definition

NLE is the statement: there is no  $\omega_1$ -iteration strategy for a premouse with a long extender on its sequence.

There is no general notion of premice with long extenders yet, but we do have a theory for premice with “not too many” long extenders. NLE says we are in the initial segment of the Wadge hierarchy below the first iteration strategy for such a premouse.

## Theorem

*Assume  $AD^+$ , and that there is an iterable premouse with a long extender. Let  $\Gamma \subseteq P(\mathbb{R})$  be such that  $L(\Gamma, \mathbb{R}) \models NLE$  ; then  $L(\Gamma, \mathbb{R}) \models HPC$ .*

In light of this theorem, the following is almost certainly true:

**Conjecture.**  $(AD^+ + NLE) \Rightarrow HPC$ .
